# Sextic Number Fields with Discriminant $-{ }^{j} \mathbf{2}^{a} \mathbf{3}^{b}$ 

John W. Jones and David P. Roberts

#### Abstract

Complete lists of number fields, of given degree $n$ and unramified outside a given finite set $S$ of primes, are both of intrinsic interest and useful in some applications. For degrees $n \leq 5$ and $S=\{\infty, 2,3\}$, the complete lists have appeared previously; there are in total 85 such fields. Here we give the complete list for $n=6$ and $S=\{\infty, 2,3\}$, finding in particular exactly 398 such fields. We use a three-pronged approach to obtain this classification: an exhaustive computer search, sextic twinning, and class field theory. Also we completely identify the 2 -adic and 3 -adic completions of all these degree $\leq 6$ fields, this information being one of the focal points of interest and essential in applications.

There is a considerable literature on the classification of number fields by means of their discriminants. At present for $n=3,4,5,6,7$ there are large tables, available at $[\mathbf{B}]$, giving all number fields of degree $n$ and absolute discriminant less than certain bounds.

It would also be interesting to have complete tables of number fields unramified outside a given finite set $S$ of primes. For a given degree $n$, these sets of number fields are finite, by a classical theorem of Hermite. For a recent survey of the general subject of number fields with prescribed ramification, we recommend $[\mathbf{H}]$; there it is made clear that very little is known about the set of non-solvable number fields unramified outside a given $S$.

In this paper, we focus on the set $S=\{\infty, 2,3\}$. We present tables for degrees $\leq$ 6 , the following chart giving an overview the situation.

| Degree $n$ | $S_{n}$ | $A_{n}$ | $H_{n}$ | Upper Bound for $\|D\|$ | Method |
| :---: | ---: | ---: | ---: | :---: | :---: |
| 2 | 7 | - | - | $2^{3} 3=24$ | Trivial |
| 3 | 8 | 1 | - | $2^{3} 3^{5}=1,944$ | Old tables or CFT |
| 4 | 22 | 1 | 39 | $2^{11} 3^{5}=497,664$ | Old tables or CFT |
| 5 | 5 | 0 | 1 | $2^{11} 3^{6}=1,492,992$ | Old tables |
| 6 | 54 | 8 | 336 | $2^{14} 3^{11}=2,902,376,448$ | New here |
| 7 |  |  |  | $2^{14} 3^{11}=2,902,376,448$ |  |
| 8 |  |  |  | $2^{31} 3^{12} \approx 1.1 \times 10^{15}$ |  |
| 9 |  |  |  | $2^{31} 3^{26} \approx 5.5 \times 10^{21}$ |  |

Here the $S_{n}$ and $A_{n}$ columns give the number of fields with the given Galois group. Similarly, the $H_{n}$ entry is the number of fields with smaller Galois group.

[^0]For $n \leq 4$, the maximal possible absolute discriminant is well within the range of the existing tables; alternatively, one can use class field theory, as all fields here are solvable. The case $n=5$ is just barely within the range of the existing tables. For $n=6$, the existing tables for arbitrary signature fields cover absolute discriminants up to 200,000; the maximum possible absolute discriminant required here is well beyond the range of these tables. The case $n=7$ may also be in the range of our current techniques, while the cases $n \geq 8$ certainly are not.

In general, we would like to advocate the point of view that number fields with discriminants divisible by only a few small primes should be regarded as "jewels". On the one hand, they occur very rarely on complete tables of number fields ordered by absolute discriminant. On the other hand, they are exactly the fields which appear most often in certain other contexts. For example, they appear as fields of definition of three-point covers of the projective line, see e.g. [Mal]. Similarly, they arise naturally in the study of motives. Suppose $M$ is a motive with bad reduction only in $S$ and $\ell$ is a finite prime in $S$; then the fields which correspond to the $\ell$-adic representations associated to $M$ are ramified only in $S$. We have already investigated some simple cases from quite varied geometric situations with $S=\{\infty, 2,3\}$. The fields we tabulate here appear repeatedly. Our tables thus play an important role in the analysis of certain motives. This application served as our principal motivation for writing the present paper.

To obtain the complete classification of sextics, we proceed as follows. There are sixteen conjugacy classes of transitive subgroups of $S_{6}$. We divide them into three classes:

- Two "new" non-solvable groups: $A_{6}$ and $S_{6}$
- Two "new" solvable groups: $C_{3}^{2} . C_{4}$ and $C_{3}^{2} . D_{4}$
- Twelve "old" groups.

We have made a large specialized computer search for fields of discriminant $-{ }^{j} 2^{a} 3^{b}$, in particular guaranteed to find all the new non-solvable fields. The search, described in Section 2, found 62 new non-solvable fields, 54 new solvable fields and 282 old fields. In Section 3.2, we use sextic twinning to directly construct all old fields from the list of degree $\leq 5$ fields; this proves that there are indeed 282 of them. In Section 3.4, we apply class field theory to the list of $C_{4}$ and $D_{4}$ quartics, proving directly that there are indeed 54 new solvable fields.

The fields we consider here being "jewels", it is worth studying them in some detail. We tabulate essentially all such fields of degree $\leq 5$ and all of the new sextic fields. These tables provide common invariants for each field, and also complete descriptions of their 2 -adic and 3 -adic completions.

## 1. Preliminaries

1.1. Conventions. A number field is by definition a finite degree field extension of $\mathbb{Q}$. Similarly, a $p$-adic field is a finite degree field extension of $\mathbb{Q}_{p}$. A number algebra is a finite direct product of number fields and a $p$-adic algebra is a finite direct product of $p$-adic fields. While the focus is on fields, it is natural, as often in Galois theory, to consider algebras as well. For example, if $K$ is a number field its $p$-adic completions $K_{p}$ are typically only $p$-adic algebras.

Throughout, when the context is clear, we will drop phrases such as "isomorphism classes of" and "up to isomorphism". For example, when we say there are
exactly 398 sextic number fields with discriminant $-{ }^{j} 2^{a} 3^{b}$, we of course mean 398 isomorphism classes of such fields.

With respect to Galois theory, we work with $\overline{\mathbb{Q}}$, the algebraic closure of $\mathbb{Q}$ in $\mathbb{C}$. We fix also algebraic closures $\overline{\mathbb{Q}}_{2} \supset \overline{\mathbb{Q}}$ and $\overline{\mathbb{Q}}_{3} \supset \overline{\mathbb{Q}}$. So we have unambiguously defined decomposition groups $D_{v}:=\operatorname{Gal}\left(\overline{\mathbb{Q}}_{v} / \mathbb{Q}_{v}\right)$ for $v=\infty, 2$, and 3 .

If $K$ is a number algebra, its root set is by definition $X:=\operatorname{Hom}(K, \overline{\mathbb{Q}})$. The construction $K \mapsto X$ gives an antiequivalence between the category of number algebras and the category of finite $\operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{Q})$-sets, number fields corresponding to transitive $\operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{Q})$-sets. The Galois group of $K$ is by definition the image of $\operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{Q})$ in the symmetric group $S_{X}$. Thus, for example, for a sextic number field $K$, one often has $\operatorname{Gal}(K) \cong S_{6}$. Similarly, one has decomposition groups $\operatorname{Gal}\left(K_{v}\right) \subseteq \operatorname{Gal}(K)$.

We do our best to consider the place $\infty$ of $\mathbb{Q}$ on an equal footing with the remaining places $2,3, \ldots$. Accordingly, for us, the discriminant of a number algebra $K$ is a formal symbol $-{ }^{j} 2^{a} 3^{b} \cdots$. Here $j$ is the number of complex places of $K$ and $a, b, \ldots$ are as usual. A place is ramified in $K$ iff the corresponding exponent is positive.

The discriminant class $d$ of a number algebra $K$ is its discriminant considered as an element of $\mathbb{Q}^{\times} / \mathbb{Q}^{\times 2}$. One can think of the discriminant class of a number field as just its discriminant with all exponents considered in $\mathbb{Z} / 2$; equivalently, one can think of a discriminant class as just a square-free integer.

The absolute discriminant of a number algebra $K$ of discriminant $D_{K}$ is just the positive integer $\left|D_{K}\right|$. We then define the root discriminant to be $\operatorname{rd}(K):=$ $\left|D_{K}\right|^{1 /[K: \mathbb{Q}]}$ and the Galois root discriminant of $K$ to be the root discriminant of a splitting field $K^{\text {gal }}$, i.e. $\operatorname{grd}(K):=\operatorname{rd}\left(K^{\text {gal }}\right)$.
1.2. Guide to the tables. Here we explain in some detail the format of Table 1. The main table of this paper, Table 6, has essentially the same format. The few differences will be explained there.

The possible Galois groups are listed on the second line of the following table.

|  | $n=3$ |  | $n=4$ |  |  |  |  |  | $n=5$ |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $G$ | $S_{3}$ | $A_{3}$ | $S_{4}$ | $A_{4}$ | $D_{4}$ | $C_{4}$ | $V$ | $S_{5}$ | $A_{5}$ | $F_{5}$ | $D_{5}$ | $C_{5}$ |  |
| $\#$ | 8 | 1 | 22 | 1 | 28 | 4 | 7 | 5 | 0 | 1 | 0 | 0 |  |

Here $F_{5}$ denotes the Frobenius group $\mathbb{F}_{5} \cdot \mathbb{F}_{5}^{\times}$of order 20 ; the other notations are standard. The third line lists the number of $-{ }^{j} 2^{a} 3^{b}$ fields with the given Galois group and degree. Table 1 omits the twenty-eight $D_{4}$ fields and the four $C_{4}$ fields; they will be tabulated along with the sextics in Table 6 , where they will play a useful role as resolvents. Table 1 also omits the seven $V$ fields; they are trivial from the point of view of classification, being naturally indexed by four-element subgroups of $\{-6,-3,-2,-1,1,2,3,6\}$.

There is a subtable for each discriminant class $d \in\{-6,-3,-2,-1,1,2,3,6\}$. After the subtable name, there are two lines of header. If $d \neq 1$, there are two lines corresponding to the quadratic field $D=\mathbb{Q}[x] /\left(x^{2}-d\right)$. Finally, there are two lines for each of the fields $K$ being tabulated.

Our policy throughout is to print invariants of $K$ so that the various aspects of our situation are each presented as clearly as possible. There are many relationships among the invariants. Often some even completely determine others, as
we'll indicate. Thus we have aimed for maximum clarity at the expense of some redundancy.

Galois groups, Artin exponents, and root numbers. Let $K$ be one of our listed fields. The entry $G$ gives the Galois group of $K$, together with some information about lifting explained below. The entries in the slots $\infty, 2,3$ are of the form $\left(c_{v}\right)_{w_{v}}$. Here $c_{v}$ is the Artin exponent at $v$; thus the discriminant of $K$ is $-{ }^{c_{\infty}} 2^{c_{2}} 3^{c_{3}}$. Also, $w_{v}$ is the root number at $v$, a fourth root of unity in $\mathbb{C}$. To save space and increase readability we use the notation

$$
\begin{array}{cccccc}
+ & \text { for } & 1 & - & \text { for } & -1 \\
i & \text { for } & i & k & \text { for } & -i .
\end{array}
$$

The root number $w_{v}(K)$ differs from the root number $w_{v}(D)$ of the quadratic discriminant algebra $D$ by a sign. Also, one always has $w_{\infty} w_{2} w_{3}=1$. The root number $w_{\infty}$ is just $k^{c_{\infty}}$, so in this spot one sees only the symbols $0_{+}, 1_{k}$ and $2_{-}$; the other root numbers are more subtle to calculate.

Quadratic lifting. For $n \geq 4$, the group $A_{n}$ has up to isomorphism a unique nonsplit double cover $\widetilde{A}_{n}$. The group $S_{n}$ has two similarly well-defined double covers restricting to $\widetilde{A}_{n}$. There are several notations for these covers in the literature, some conflicting. We let $\widetilde{S}_{n}$ be the double cover where 2 -cycles in $S_{n}$ lift to elements of order two; we let $\widehat{S}_{n}$ be the double cover where 2 -cycles in $S_{n}$ lift to elements of order 4. Given a degree $n$ number algebra $K$ with root set $X=\operatorname{Hom}(K, \overline{\mathbb{Q}})$, the permutation representation $\rho_{K}: \operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{Q}) \rightarrow S_{X}$ may or may not lift to $\widetilde{S}_{X}$; similarly, it may or may not lift to $\widehat{S}_{X}$.

Lifting criteria in two related languages are given in $[\mathbf{S}]$ and $[\mathbf{D}]$. Very simply,

$$
\begin{aligned}
& \rho_{K} \text { lifts to a } \tilde{\rho}_{K} \Longleftrightarrow \forall v, w_{v}(K)=w_{v}(D) \\
& \rho_{K} \text { lifts to a } \hat{\rho}_{K} \Longleftrightarrow \forall v, w_{v}(K)=w_{v}(D)(d,-1)_{v}
\end{aligned}
$$

Here $(d,-1)_{v} \in\{ \pm 1\}$ is the Hilbert sign. For convenience, on the discriminant class $d$-table we have put the header $v$ in bold-face iff $(d,-1)_{v}=-1$. If $K$ has Galois group $G$, we write $G, \widetilde{G}, \widehat{G}$ or $\bar{G}$ to indicate whether one has no lifting, tilde-lifting only, hat-lifting only, or both liftings. Perhaps the most interesting fact about the seven omitted $V$ quartics is the following. Since $V$ is a subgroup of the alternating group $A_{4}$, the tilde and hat obstructions coincide for each place $v$; they all vanish only for $\mathbb{Q}(\sqrt{2}, \sqrt{3})$, and so this field only is contained in quaternionic octic fields. In fact, $\mathbb{Q}(\sqrt{2}, \sqrt{3})$ is contained in two such $-{ }^{j} 2^{a} 3^{b}$ fields, one totally real and the other totally imaginary.

Slope content. In the slot $S C_{p}$, we give the slope content of $K_{p}$ at $p$. By this we mean the following. The decomposition group $D_{p}=\operatorname{Gal}\left(K_{p}\right)$ has a decreasing filtration by ramification groups which we index using the Artin upper numbering system. The slopes of $D_{p}$ are the indices $c$ of the non-trivial subquotients $Q_{p}^{c}=D_{p}^{c} / D_{p}^{>c}$. The group $Q_{p}^{0}=D_{p} / I_{p}$, which corresponds to unramified extensions, is cyclic; the group $Q_{p}^{1}$, which corresponds to tame ramification, is cyclic of order prime to $p$; the groups $Q_{p}^{c}$ for $c>1$ correspond to wild ramification and are elementary abelian $p$-groups.

We define the slope content of $K_{p}$ to be a set, allowing multiplicities, of ordered pairs $\left(c_{i}, p_{i}\right)$, having the following property. The $p_{i}$ are prime and for all slopes $c$,

$$
\prod_{c_{i}=c} p_{i}=\left|Q_{p}^{c}\right|
$$

Thus our terminology "slope content" is in the spirit of "Jordan-Hölder content".
The primes $p_{i}$ which appear here are 2,3 , and 5 . Exploiting this fact we merely print the $c_{i}$ in decreasing order using the following conventions. The prime $p_{i}=5$ occurs only for the unique $F_{5}$ field, and we print the corresponding $c_{i}$ in boldface. When $p_{i}=p$, we print $c_{i}$ in plain type. Otherwise, we print $c_{i}$ in italics. There are in fact only the following possibilities for the $c_{i}$, and we use abbreviations as follows:

| At 2 | At 3 |
| :---: | :---: |
| 0 | 0 |
| 0 | 0 |
| 1 | 1 |
| $4 / 3,4 / 3=[4 / 3]$ | 1 |
| 2 | $5 / 4,5 / 4=[5 / 4]$ |
| 8/3, $8 / 3=[8 / 3]$ | $3 / 2=\mathrm{t}$ |
| 3 | 2 |
| $7 / 2=\mathrm{s}$ | $9 / 4,9 / 4=[9 / 4]$ |
| 4 | $5 / 2=\mathrm{f}$ |

Here whenever the slopes $4 / 3,8 / 3,5 / 4$, or $9 / 4$ appear, they appear with multiplicity two, allowing our abbreviations. For example, an entry [8/3] 10 indicates in particular that $\left|D_{2}\right|=24$ and $\left|I_{2}\right|=12$; in fact here one has $D_{2} \cong S_{4}$ and $I_{2} \cong A_{4}$.

Galois root discriminants. An irreducible linear representation

$$
\rho: D_{p} \rightarrow \operatorname{Aut}(V)
$$

of $D_{p}$ has a slope $s(\rho)$, namely the smallest $c \in[0, \infty)$ with $D_{p}^{>c}$ in the kernel of $\rho$. The Artin exponent $c(\rho)$ of $\rho$ is then the slope $s(\rho)$ times the degree $\operatorname{dim}(V)$. Artin exponents of arbitrary representations are then defined by additivity. If $\rho$ is induced from a permutation representation $r: D_{p} \rightarrow S_{X}$, then the discriminant of the $p$-adic algebra $K_{p}$ corresponding to $X$ is $p^{c(\rho)}$.

In the slot grd, we give the Galois root discriminant $\delta=2^{\alpha} 3^{\beta}$ of $K$ to two decimal places. Here $\alpha$ is calculated as the mean slope of $D_{2}$ acting on itself by left translations; similarly, $\beta$ as the mean slope of $D_{3}$ acting on itself by left translations. Thus, for example, suppose in $S C_{2}$ we have printed [8/3] 10 . Of the twenty-four slopes, three-quarters are $8 / 3$, one-sixth are 1 , and one-twelfth are 0 ; this yields the average $\alpha=13 / 6 \approx 2.17$.

Fields with the same Galois group and resolvent are sorted by increasing Galois root discriminant. Fields with small root discriminant are interesting for a number of reasons; for examples constructed from the fields here, see [R1].

Class numbers. In the slot $h$ we have printed the class number of $K$ when different from 1.

A defining equation. The next block gives the coefficients $a_{i}$ of a polynomial

$$
f(x)=x^{n}+a_{1} x^{n-1}+\cdots+a_{n-1} x+a_{n} \in \mathbb{Z}[x]
$$

with $K=\mathbb{Q}[x] / f(x)$ the field under consideration. Here, for almost-canonicity, we have chosen $f$ so that the sum $T_{2}(f)$ is minimal. If $\alpha_{i}$ are the complex roots of $f$,

$$
T_{2}(f):=\sum_{i=1}^{n}\left|\alpha_{i}\right|^{2}
$$

2-adic and 3-adic information. The next two blocks of data for $K$ give information about the $p$-adic algebra $K_{p}$, for $p=2$ and then $p=3$. We will describe these two blocks in parallel. The algebra $K_{p}$ has the form

$$
K_{p}=K_{p}^{1} \times K_{p}^{2} \times \cdots
$$

each of the factors being fields, say of weakly decreasing degree. There is one line of data for each field different from $\mathbb{Q}_{p}$. Thus, here there can be at most two lines of data. Note that even on Table 6 , the a priori possibility that $K_{p}$ is the product of three quadratic fields in fact does not occur.

The entry $f^{e}$ gives the inertial degree $f$ and the ramification index $e$; thus the degree of the field is the product $f e$. The entry $c_{w}$ gives the Artin exponent $c$ and the root number $w$ of the local field $K_{p}^{j}$. The entry $d$ gives the discriminant class of $K_{p}^{j}$. Here the natural map $\{-6,-3,-2,-1,1,2,3,6\} \rightarrow \mathbb{Q}_{2}^{\times} / \mathbb{Q}_{2}^{\times 2}$ is conveniently bijective; we thus use these labels even in the current local context. On the other hand, the natural map $\{-6,-3,-2,-1,1,2,3,6\} \rightarrow \mathbb{Q}_{3}^{\times} / \mathbb{Q}_{3}^{\times 2}$ is surjective with kernel $\{1,-2\}$. Here we use the labels $\{-3,-1,1,3\}$ - one needs to always remember that it is -2 and not 2 that is trivial.

If there is no proper quadratic subfield of $K_{p}^{j}$, the entry $s$ is left blank. If there is exactly one proper quadratic subfield, the entry $s$ gives its discriminant class. The only other possibility is that there are three quadratic subfields of $K_{p}^{j}$; then $K_{p}^{j}=K_{p}^{1}$ is quartic with Galois group $V$. There are seven $V$ quartics over $\mathbb{Q}_{2}$; but it happens that none of them appear as a $K_{2}^{1}$ for a field $K$ on either of our tables. There is one $V$ quartic over $\mathbb{Q}_{3}$; this appears as $K_{3}^{1}$ on our tables just for three $D_{4}$ quartics; in this case, we print $V$ in the column $s$.

The paper $[\mathbf{R 2}$ ] tabulates all 2 -adic and 3 -adic fields of degree $\leq 6$. The data $\left(f^{e}, c_{w}, d, s\right)$ often suffice to determine $K_{p}^{j}$ up to isomorphism. In degrees $\leq 5$ there can be otherwise only a 2 -fold or a 3 -fold ambiguity. In these cases, we add an identifying label from $\{x, y\}$ or from $\{a, b, c\}$, according to the scheme in [R2].

The local information just described in fact determines most of the information in the first block of data. Namely the Artin exponent $c_{p}$ decomposes additively while the root number $w_{p}$ and the discriminant class $d$, considered in $\mathbb{Q}_{p}^{\times} / \mathbb{Q}_{p}^{\times 2}$, decompose multiplicatively. For example, for the quartic $S_{4}$ field with discriminant $-{ }^{2} 2^{5} 3^{5}$, and thus discriminant class $d=6$, the decompositions at $p=2$ are

$$
\begin{aligned}
c: & & 5=2+3 \\
w: & & i=i \cdot 1 \\
d: & & 6=3 \cdot 2 .
\end{aligned}
$$

Note that for $\mathbb{Q}_{p}$ the relevant invariants are trivial: $c=0, w=1$, and $d=1$.
This local information also determines the slope content in a less direct way. For example, suppose $n=4$ and $K_{2}$ is a field. If $c=9$ or 10 , then the slope content is s 32 . If $c=11$, then the slope content is 43,430 , or 432 , according to whether the product discriminant class $s d$ is $1,-3$, or -1 .

Frobenius data. The last block of data gives the Frobenius elements $\operatorname{Fr}_{p}$ for $p=5,7, \ldots, 47$, as partitions of the degree $n$. To save space, we do not print 1's: thus the partition $4=2+1+1$ gets printed just as 2 . This information is essential for identifying fields involved in the 2 -adic or 3 -adic representations associated to a motive. For given a motive, one typically has direct access only to Frobenius data, not to discriminantal data, and certainly not to defining equations.
1.3. Table for degrees $\leq \mathbf{5}$. Table 1 presents the complete table of cubics, quartics, and quintics with discriminant $-{ }^{j} 2^{a} 3^{b}$, excluding the $V, C_{4}$, and $D_{4}$ quartics as has been explained. As emphasized in the introduction, this list of fields is not new. The list of nine cubics is given in [MS], where these nine fields are studied in considerable detail. All but one of the cubics, quartics, and quintics appear on the large lists available in Pari format by anonymous ftp from $[\mathbf{B}]$. The one exception is the highest discriminant quintic, which is covered by [SPD]. On the other hand, these large lists do not provide all the information that Table 1 does.

Among several things to note in Table 1, we'll just mention one. There are eight $S_{3}$ cubics and one $A_{3}$ cubic. For all but one of these cubics $F$, the 3-decomposition group $\operatorname{Gal}\left(F_{3}\right)$ coincides with global Galois group $\operatorname{Gal}(F)$. The exception is the unique cubic with discriminant class -2 , for which the 3-local-to-global inclusion is $A_{3} \subset S_{3}$. Now up to conjugation there are just two subgroups of $S_{4}$ surjecting down to $S_{3}$ under the resolvent map, namely $S_{4}$ itself and $S_{3} \subset S_{4}$. Similarly, there are just two subgroups of $S_{4}$ surjecting to $A_{3}$, namely $A_{4}$ and $A_{3} \subset A_{4}$. Now neither $S_{4}$ nor $A_{4}$ is of the form 3-group by $3^{\prime}$-cyclic by cyclic; so they are not quotients of $\operatorname{Gal}\left(\overline{\mathbb{Q}}_{3} / \mathbb{Q}_{3}\right)$. In conclusion, the 3-completion of all of our $A_{4}$ or $S_{4}$ quartics $K$ has the form $\mathbb{Q}_{3} \times F_{3}$ where $F_{3}$ is the completion of the resolvent cubic $F$. This explains the repetitiveness of the 3-local block of columns.

## 2. Targeted searches

Let $n$ and $D$ be positive integers. There is a standard method by which one can make systematic searches for all primitive number fields of degree $n$ and absolute discriminant $\leq D$. Here we quickly review this method. Then we explain, in more detail, how one can modify it to make much quicker searches for primitive degree $n$ number fields with absolute discriminant exactly $D$. It is a question of

TABLE 1. Low degree fields (Galois group $\neq V_{4}, C_{4}$, or $D_{4}$ )

supplementing the usual archimedean bounds on coefficients with $p$-adic bounds for each prime $p$ dividing $D$. Throughout, we illustrate the generalities with our particular case $n=6$ and $D$ of the form $2^{a} 3^{b}$.

Let $K$ a number field of the type sought: primitive, degree $n$, and with absolute discriminant $D$. Let $\mathcal{O}_{K}$ be its ring of integers and $I$ the product of all prime ideals in $\mathcal{O}_{K}$ over primes $p$ dividing $D$. For $\eta \in I$ one has its characteristic polynomial

$$
f_{\eta}(x)=x^{n}+a_{1} x^{n-1}+a_{2} x^{n-2}+\cdots+a_{n-1} x+a_{n} \in \mathbb{Z}[x] .
$$

In $\S 2.1$, we state a version of Hunter's theorem adapted to this context. It guarantees the existence of one $\eta \in I-\mathbb{Z}$ with the corresponding coefficients $a_{i}$ satisfying a certain quite complicated system of inequalities. In $\S 2.2$, we introduce integers $v_{p, i}$. They are the largest integers such that every $\eta \in I$ satisfies the congruence $p^{v_{p, i}} \mid a_{i}$. Details of our computer search are given in $\S \S 2.3-2.4$, and possible improvements in §2.5.
2.1. Archimedean bounds. The traditional statement of Hunter's theorem involves the full ring of integers $\mathcal{O}_{K}$. For targeted searches, we use the completely analogous statement for our search ideal $I$.

Theorem 2.1. Let $K$ be a degree $n$ number field with absolute discriminant $D$. Let $l$ be the least positive integer contained in $I$ and let $m$ be the order of $\mathcal{O}_{K} / I$. Finally, let $\gamma_{n}$ be Hermite's constant for $n$-dimensional lattices. Then there exists an element $\eta \in I-\mathbb{Z}$ such that

$$
T_{2}\left(f_{\eta}\right) \leq \frac{\operatorname{Tr}(\eta)^{2}}{n}+\gamma_{n-1}\left(\frac{m^{2} D}{l^{2} n}\right)^{1 /(n-1)}
$$

and $0 \leq \operatorname{Tr}(\eta) \leq[n l / 2]$.
For $I=\mathcal{O}_{K}$, this is the usual statement of Hunter's theorem as it appears, for example, in $[\mathbf{C}]$. The new factor $m^{2} / l^{2}$ in the discriminant term gives in practice much weaker archimedean bounds. The ultrametric bounds in $\S 2.2$ more than make up for this loss. As in the case when $I=\mathcal{O}_{K}$, search times are dependent essentially on only the discriminant term. In our searches, $n=l=6$ and Hermite's constant $\gamma_{5}=\sqrt[5]{8}$, so the discriminant term is $\left(m^{2} D / 27\right)^{1 / 5}$.

The transition from this bound on $T_{2}\left(f_{\eta}\right)$ to explicit bounds on the coefficients of $f_{\eta}$ is very subtle and a point of continuing research. In our computer program we use the methods described in $[\mathbf{P}, \S 3]$.

Remark 2.2. We are interested in both primitive fields and imprimitive fields, yet the version we have stated of Hunter's theorem is not suitable for classifying imprimitive fields $K$. The problem is that the element $\eta$, whose existence is being asserted, might lie in a proper subfield of $K$. There is a version of Hunter's theorem which applies to imprimitive fields due to Martinet [Mar]. However our search for primitive fields in fact found all imprimitive fields as well, as we will prove by sextic twinning and class field theory in $\S 3$.
2.2. Ultrametric bounds. Fix $p$ dividing the targeted absolute discriminant $D$; thus, $p=2$ or $p=3$ for the computer search conducted for this paper. Let $c$ be the Artin exponent at $p$, so that $p^{c}$ exactly divides $D$. The considerations of this section are purely $p$-adic; we consider $p$-adic algebras $K_{p}$ of degree $n$ and discriminant $p^{c}$.

The target $p^{c}$ is best thought of as composed of several smaller targets. Accordingly, one aims at these smaller targets separately as follows. Let $\mathbb{Q}_{p}^{\text {un }}$ be a maximal unramified extension of $\mathbb{Q}_{p}$. Consider the base-changed algebra $K_{p}^{\text {un }}=K_{p} \otimes \mathbb{Q}_{p}^{\text {un }}$. It has a canonical decomposition into fields:

$$
K_{p}^{\mathrm{un}}=K_{p}^{\mathrm{un}, 1} \times \cdots \times K_{p}^{\mathrm{un}, w}
$$

Here we let $e_{j}$ be the degree of $K_{p}^{\text {un, } j}$ over $\mathbb{Q}_{p}^{\text {un }}$ and $c_{j}$ its Artin exponent. Thus $\sum e_{j}=n$ and $\sum c_{j}=c$. We define a ramification structure to be a set of pairs
which can arise in this way, allowing multiplicities of course:

$$
r=\left\{\left(e_{1}, c_{1}\right), \ldots,\left(e_{w}, c_{w}\right)\right\}
$$

These ramification structures are the smaller targets.
Let $K_{p}$ be a degree $n$ algebra with ramification structure $r$ as above, say written with the $e_{i}$ weakly decreasing. Let $I_{p}$ be the product of the maximal ideals in $\mathcal{O}_{K_{p}}$; this is now our local search ideal. Let $\eta \in I_{p}$ with characteristic polynomial $f_{\eta}(x)=x^{n}+a_{1} x^{n-1}+\cdots+a_{n}$. From the $e_{i}$ 's alone, one knows that $p^{u_{i}} \mid a_{i}$ where

$$
u_{i}=\min \left\{u: \sum_{1}^{u} e_{j} \geq i\right\}
$$

These congruences are usually phrased in terms of Newton polygons: $u_{i}$ is the smallest integer such that $\left(i, u_{i}\right)$ is on or above the Newton polygon of $K_{p}$.

Recall that if $p \nmid e_{j}$ the field $K_{p}^{\mathrm{un}, j}$ is tame, and very simply $c_{j}=e_{j}-1$. If $p \mid e_{j}$ then the field $K_{p}^{\mathrm{un}, j}$ is wild; its Artin exponent $c_{j}$ is one of finitely many possibilities, the smallest being $e_{j}$ and the largest being $\operatorname{ord}_{p}\left(e_{j}\right) e_{j}+e_{j}-1$.

Define $v_{i}$ to be the largest integer such that $p^{v_{i}} \mid a_{i}$ for all $\eta$ in the search ideal $I_{p}$ of any algebra $K_{p}$ with the given ramification structure $r$. When each $c_{j}$ is minimal for $e_{j}$ one has very simply $v_{i}=u_{i}$. When some $c_{j}$ are non-minimal one may have $v_{i}>u_{i}$ for some $i$. We call the $v_{i}$ Newton-Ore exponents because of the connection with both Newton polygons and Ore's formulas for discriminants of Eisenstein polynomials [Or].

For $r=\{(n, c)\}$, corresponding to totally ramified fields, the Newton-Ore exponents have been described in many places; the discussion in [R2] gives examples particularly relevant for this paper. For $r=\left\{\left(e_{1}, c_{1}\right), \ldots,\left(e_{w}, c_{w}\right)\right\}$, the numbers $v_{i}$ are computed by examining the coefficients of $f_{1} \cdots f_{w}$; here $f_{j}$ has degree $e_{j}$ and is the general polynomial with coefficients satisfying the corresponding Newton-Ore congruences; a particular case is examined closely in $\S 2.5$ below.

We have calculated the Newton-Ore exponents for all possible sextic ramification structures $\left\{\left(e_{1}, c_{1}\right), \ldots,\left(e_{w}, c_{w}\right)\right\}$, treating the cases $p=2$ and $p=3$ separately. Tables 2 and 3 record some of the results. Here is an example, which illustrates how to read the tables. Take $p=2$ and $r$ of the form $\{(6, c)\}$, corresponding to totally ramified sextics. The relevant column is $6_{c}$; in general, the tables present ramification structures as subscripted partitions of 6 . The possible values for the Artin exponent $c$ are $6,8,10$, and 11. If $c$ is 6 , one has only the Newton congruences $2 \mid a_{1}, a_{2}, a_{3}, a_{4}, a_{5}, a_{6}$. Table 2 shows the exponents $v_{i}$ in sequence, 111111. As $c$ increases one gets stronger congruences until for $c=11$ one has $2 \mid a_{2}, a_{4}, a_{6}$ and $4 \mid a_{1}, a_{3}, a_{5}$, which Table 2 records as 212121.
2.3. Combining cases. There are 37 sextic ramification structures at $p=2$ and 24 sextic ramification structures at 3 . So there are $37 \cdot 24$ searches to be done, each with its own archimedean and ultrametric bounds. However many of our smaller searches are rendered unnecessary by our larger searches, as we explain now.

Fix a ramification structure

$$
r=\left\{\left(e_{1}, c_{1}\right), \ldots,\left(e_{w}, c_{w}\right)\right\}
$$

with Artin exponent $c=\sum c_{i}$. Let

$$
v=\left(v_{1}, v_{2}, \ldots, v_{6}\right)
$$

|  |  |  |  | 3,4 | $"$ | 11 | 13 | 6 | 111111 | 8 | 10 |
|  |  |  |  | 3,3 | $"$ | 10 | 11 |  |  |  |  |

be the associated sequence of Newton-Ore exponents; so $v_{6}=w$. The ramification structure $r$ contributes $p^{2 v_{6}+c}$ to the critical quantity $m^{2} D$ in Hunter's theorem. The exponent $2 v_{6}+c$ has been printed in Tables 2 and 3 , under the heading $\alpha_{1}$ or $\beta_{1}$.

Consider another ramification structure $R=\left\{\left(E_{1}, C_{1}\right), \ldots,\left(E_{W}, C_{W}\right)\right\}$, inducing the Artin exponent $C$ and the Newton-Ore exponents $\left(V_{1}, \ldots, V_{6}\right)$. We say that $R$ subsumes $r$ iff

$$
\begin{gathered}
V_{i} \leq v_{i} \quad \text { for all } i=1, \ldots, 6 \\
2 V_{6}+C \geq 2 v_{6}+c .
\end{gathered}
$$

We write $r \preceq R$ to indicate this relationship. The point is that the search for all $R_{2}-R_{3}$ fields finds also all $r_{2}-r_{3}$ fields if $r_{2} \preceq R_{2}$ and $r_{3} \preceq R_{3}$.

For example, on the above table any ramification pattern $r_{p}$ indicated by quotes is subsumed by the ramification pattern $R_{p}$ above it, to which the quotes refer. Also, one has the five indicated relations $w_{1} \preceq W, w_{2} \preceq W, \ldots, z \preceq Z$. In particular, the entire column $3_{c} 111$ for $p=3$ is subsumed by other entries. Among the 37 ramification patterns at 2 , the maximal ones are exactly the 8 patterns maximal on Table 2; similarly, among the 24 ramification patterns at 3 , the maximal ones are exactly the 8 patterns which are maximal on Table 3 . Thus, we in fact carry out $64=8 \cdot 8$ separate searches, rather than $888=37 \cdot 24$ searches.
2.4. The computer searches. Each of the 64 searches was carried out in two stages. The program for the first stage was written in C, utilizing the Pari programming library, and was implemented on several Sun and HP workstations. The program was designed to find all sextic monic polynomials in $\mathbb{Z}[x]$ with coefficients $a_{i}$ satisfying the archimedean, 2 -adic, and 3 -adic inequalities discussed above. By far, this was the more time-consuming stage.

The second stage checked for irreducibility on early polynomials, as defined below. It then eliminated duplicate fields, and generated most of the information found in Tables 1 and 6.

The first stage ran each polynomial $f$ through the following screening procedure.

1. Compute the absolute polynomial discriminant of $f$, and divide out all factors of 2 and 3 . If the result is 1 , output $f$ to stage 2 . If the result is a square different from 1 , pass $f$ on to step 2 .
2. Pass $f$ to step 3 iff $T_{2}(f)$ is below the Hunter bound.
3. Pass $f$ to step 4 iff $f$ is irreducible.
4. Output $f$ to stage 2 iff the absolute field discriminant $\left|D_{K(f)}\right|$ is of the form $2^{a} 3^{b}$.
The order of the tests above is important, typical times for Test $i$ being very roughly as given in the second column of Table 4; these times are averages based on 1000 sample polynomials. The third and fourth columns give some data for 2 of

Table 4. Timing data

|  | Time per <br> polynomial | $6_{11}$ at 2 <br> $6_{10}$ at 3 | $6_{11}$ at 2 <br> $3_{5} 3_{5}$ at 3 |
| ---: | :---: | ---: | ---: |
| Test 1: | 0.0013 Seconds | 1017101 | 1301618 |
| Test 2: | 0.055 Seconds | 4014 | 4779 |
| Test 3: | 0.104 Seconds | 1438 | 2194 |
| Test 4: | 0.128 Seconds | 1383 | 2064 |
| Late Fields Found | 140 | 203 |  |
| Early Fields Found | 384 | 402 |  |
| Distinct Fields Found | 229 | 215 |  |
| Distinct Fields on Target | 1 | 11 |  |

our 64 searches. The first line gives the number of polynomials inspected, i.e. the number to which we applied Test 1. The second line gives the number which passed Test 1 to which we then applied Test 2, and so on. Late fields found indicates the number of polynomials output by Test 4, whereas early fields found indicates the number of irreducible polynomials output by Test 1. Distinct fields found represents the result of combining early and late fields and removing duplicates, while distinct fields on target represents those which match the targeted ramification structure.

Note that Test 1 is not available when one is looking simply for all fields of degree $n$ with absolute discriminant less than a given bound $D$; so here we have an important time savings inherent in targeted searches. As the numbers indicate, relatively few polynomials need further testing.

The entries $\alpha$ and $\beta$ in Tables 2 and 3 are calculated by $\alpha=2 \alpha_{1}-\sum v_{2, i}$ and $\beta=2 \beta_{1}-\sum v_{3, i}$. The time required for a given case is roughly proportional to the number of polynomials inspected, which is in turn proportional to $2^{\alpha} 3^{\beta}$. Our searches for the longest cases, namely $4_{11} 2_{c}$ at 2 versus $6_{11}$ at 3 , for $c=2,3$, inspected approximately half a billion polynomials each.

Remark 2.3. The following brief discussion of the large drop $229 \rightarrow 1$ on Table 4 throws some further light on the nature of our search. To search for fields with ramification structure $6_{11}$ at 2 and $6_{10}$ at 3 , we imposed the congruences $4 \mid a_{1}$,
$a_{3}, a_{5}, 2\left|a_{2}, a_{4}, a_{6}, 3\right| a_{1}, a_{3}, a_{6}$, and $9 \mid a_{2}, a_{4}, a_{5}$, in accordance with Tables 2 and 3. Normalize Haar measure so that the corresponding region $R$ in $\mathbb{Z}_{2}^{6} \times \mathbb{Z}_{3}^{6}$ has total mass one. Let $T \subset R$ be the subregion of $R$ consisting of polynomials with exactly the targeted ramification structure. The region $T$ contains $T_{0}$ which is defined by the additional conditions $4 \nmid a_{6}$ ("Eisenstein at 2 "), $9 \nmid a_{6}$ ("Eisenstein at 3 "), and $9 \nmid a_{1}$ (forcing $c_{3}=10$ rather than $c_{3}=11$ ). The mass of $T_{0}$ is $(1 / 2)(2 / 3)(2 / 3)=2 / 9$.

In searching all of $R$, rather than just the target $T$, we are over-searching by a factor of less than 4.5 , reasonable given the circumstances. In the region $T$, in fact $T_{0}$, we found exactly the one targeted field, listed as the second $S_{6}$ field on our $d=2$ subtable. In retrospect one sees that our search over $R$ found more than half of the 398 sextic fields with discriminant $-{ }^{j} 2^{a} 3^{b}$. This fact serves as a reminder that it is relatively easy to produce many sextic fields with discriminant $-{ }^{j} 2^{a} 3^{b}$; the deep assertion in this paper is that we have found all such sextic fields.
2.5. Improvements. Our search was carried out using easy-to-program bounds, but by no means optimal bounds. For larger $n$ and/or larger targeted absolute discriminant $D$ it would be important to use better bounds.

Better archimedean bounds. This has been explored by several papers, e.g. [SPD]. The best results target the different possible ramification patterns $-{ }^{j}$ separately. For $j=0$, i.e. the totally real case, this is a very substantial savings. As $j$ increases, the savings becomes more modest. Our archimedean bounds were actually moderately close to optimal since roughly one-third of the polynomials $f$ we inspected indeed had $T_{2}(f)$ under the search bounds.

Better ultrametric bounds. When the target ramification structures are totally ramified, our use of coefficient-by-coefficient congruences only is reasonably close to optimal, as illustrated by Remark 2.3. However in general, it would be important to take advantage of other more complicated congruences as we indicate by the following example.

Take $p=2$ and target the ramification structure $4_{11} 2_{2}$. The relevant product is then

$$
\begin{aligned}
& \left(x^{2}+2 a x+2 b\right)\left(x^{4}+8 A x^{3}+4 B x^{2}+8 C x+2 D\right) \\
& =x^{6}+2(a+4 A) x^{5}+2(b+2 B+8 a A) x^{4}+8(a B+C+2 A b) x^{3} \\
& \quad+2(D+4 b B+8 a C) x^{2}+4(a D+4 b C) x+4(b D)
\end{aligned}
$$

We used only the obvious congruences $2^{v_{i}} \mid a_{i}$ with $\left(v_{1}, v_{2}, v_{3}, v_{4}, v_{5}, v_{6}\right)=$ $(1,1,3,1,2,2)$, as stated in Table 2. Thus we searched over a lattice with coordinates

$$
\begin{array}{ll}
b_{1}=a+4 A & b_{2}=b+2 B+8 a A \\
b_{3}=a B+C+2 A b & b_{4}=D+4 b B+8 a C \\
b_{5}=a D+4 b C & b_{6}=b D .
\end{array}
$$

Among the congruences we did not exploit are the following.

$$
b_{5} \equiv b_{1} b_{4}
$$

$$
\begin{array}{ll}
\text { If } b_{4} \equiv 1 & (2) \text { then } b_{6} \equiv b_{2} b_{4} \\
\text { If } b_{4} \equiv 0 & (2) \text { then } b_{6} \equiv b_{2} b_{4} \tag{4}
\end{array}
$$

In fact, these are all the congruences modulo 4. Namely, as $(a, b, A, B, C, D)$ runs over the 4096 elements of $(\mathbb{Z} / 4)^{6}$, the vector $\left(b_{1}, b_{2}, b_{3}, b_{4}, b_{5}, b_{6}\right)$ runs over exactly the 384 elements of $(\mathbb{Z} / 4)^{6}$ satisfying these congruences. So the incorporation of just these congruences into the program would give a time savings of roughly a factor of 10 for the cases involving the ramification structure $4_{11} 2_{2}$ at 2 .

## 3. Sextics

In $\S 3.1$, we give the complete breakdown of the 398 fields found by the computer search according to Galois group and discriminant class. In $\S 3.2$, we prove that the list of 282 old sextic fields is complete using the tables of smaller degree fields from $\S 1.3$ and sextic twinning. In $\S 3.3$, we tabulate the 116 new sextic fields. Finally in $\S 3.4$, we prove that the list of new solvable sextic fields is complete using class field theory.
3.1. Summarizing table. The sextic twinning operator $t$ is treated in detail in $[\mathbf{R 3}]$. Here we review just enough for our purposes. If $X$ is a six element set, one has canonically a second six-element set $X^{t}$ with a natural bijection $X \rightarrow X^{t t}$. Correspondingly, if $K$ is a sextic separable algebra over a field $F$ then one has its twin algebra $K^{t}$. The Galois groups $G$ of $K$ and $G^{t}$ of $K^{t}$ are identical as quotient groups of $\operatorname{Gal}(\bar{F} / F)$; however the permutation representations $X$ and $X^{t}$ are not isomorphic, except in degenerate cases where the Galois group is very small. Given a defining polynomial of a sextic separable algebra, a defining polynomial for its twin algebra can be computed as a resolvent sextic for the subgroup $P G L_{2}(5) \subset S_{6}$.

If $K$ is a field, there are two possibilities. First, its Galois group $G$ may be $C_{3}^{2} . C_{4}, C_{3}^{2} . D_{4}, A_{6}$, or $S_{6}$. In this case, $K^{t}$ is a field not isomorphic to $K$. These "new" fields thus come in twin pairs. Second, the Galois group $G$ may be one of the remaining twelve transitive subgroups of $S_{6}$. In this case $K^{t}$ is not a field, its Galois group $G^{t}$ not being transitive. Thus these "old" fields are by definition constructible from fields of smaller degree.

Table 5 gives, for each of the 16 transitive subgroups $G$ of $S_{6}$, and each of the eight possible discriminant classes $d \in\{-6,-3,-2,-1,1,2,3,6\}$, the number of sextic fields with Galois group $G$ and discriminant class $d$ found by the search. The top block summarizes Table 1. The format is similar to the next three blocks which we describe now. In the column headed by $G$, we list the 11 transitive subgroups of $S_{6}$ which are not in $A_{6}$. The column labeled by $G_{+}$gives information about $G \cap A_{6}$. In five cases this subgroup is not transitive; then the entry is left blank. In six cases the subgroup is transitive; then it is given, with the unique exception of the even subgroup of $S_{2} \imath^{\epsilon} S_{3}$. This subgroup is $S_{2} \imath^{+} A_{3}$ which has already appeared as the even subgroup of $S_{2}$ 亿 $A_{3}$. Our notation for subgroups follows $[\mathbf{R 3}]$ and, in particular, "?" indicates a wreath product.

On the $G$ row, we have also printed $\left(G_{+}^{t} \subset\right) G^{t}$. Here $G=G^{t}$ but $G$ is acting on a six element set $X$, while $G^{t}$ is acting on the six element set $X^{t}$. In the old cases, the action of $G^{t}$ is intransitive, and the subscripts indicate the orbit structure, fixed points not being mentioned. For example, $D_{6}=S_{3} S_{2}$ acts transitively on $X$ and with orbit partition 321 on $X^{t}$.

Finally in the $G$ row, the entries under $d \neq 1$ refer to $G$, while the entry under $d=1$, when non-blank, refers to $G_{+}$. Thus the sum of the sixteen numbers in boldface corresponding to sextics is the number of sextic fields with discriminant ${ }^{j} 2^{a} 3^{b}$ found by the search, namely 398.

TABLE 5. Summarizing table for degrees $\leq 6$

| $12 \quad 24$ | $S_{2} 乙^{+} A_{3} \subset S_{2} \backslash A_{3}$ | $A_{4} \subset A_{4} S_{2}$ | $\begin{array}{llll}1 & 1 & 1 & 1\end{array}$ |  |  | $1 \begin{array}{ll}1 & 1\end{array}$ | 7 |
| 24 | $\subset S_{2} 2^{\epsilon} S_{3}$ | $\subset S_{4}$ | $\begin{array}{llll}3 & 6 & 3 & 3\end{array}$ |  |  | $\begin{array}{ll}0 & 7\end{array}$ | 22 |
| $24 \quad 48$ | $S_{2} \imath^{+} S_{3} \subset S_{2}$ 乙 $S_{3}$ | $S_{4}^{+} S_{2} \subset S_{4} S_{2}$ | $\begin{array}{lllll}19 & 16 & 19 & 19\end{array}$ |  |  | 2215 | 132 |
| 60120 | $\mathrm{PSL}_{2}(5) \subset \mathrm{PGL}_{2}(5)$ | $A_{5} \subset S_{5}$ | $\begin{array}{lllll}1 & 0 & 0 & 0\end{array}$ | 0 | 2 | $1 \begin{array}{ll}1 & 1\end{array}$ | 5 |
| New solvable sextics |  |  |  |  |  |  |  |
| $\begin{array}{ll}36 & 72\end{array}$ | $C_{3}^{2} . C_{4} \subset C_{3}^{2} . D_{4}$ | $C_{3}^{2} . C_{4} \subset C_{3}^{2} . D_{4}$ | $\begin{array}{lllll}10 & 10 & 4 & 18\end{array}$ | 4 | 8 | $0 \quad 0$ | 50 |
| New non-solvable sextics |  |  |  |  |  |  |  |
| 360720 | $A_{6} \subset S_{6}$ | $A_{6} \subset S_{6}$ | $2 \begin{array}{llll}2 & 0 & 4\end{array}$ | 82 | 26 | 812 | 54 |

In the case of sextic fields, one has something of a coincidence: a transitive subgroup of $S_{6}$ is primitive iff it is non-solvable. Thus the computer search was guaranteed to find all the fields only in the cases $G=\mathrm{PSL}_{2}(5), \mathrm{PGL}_{2}(5), A_{6}$, and $S_{6}$.
3.2. Old fields. Here we use Table 1 and sextic twinning to prove that the numbers of old sextic fields presented in the previous section are correct, giving a total of 282 old sextic fields. This shows that the computer search, which was not guaranteed to find all old fields, in fact did. We then give a short table giving defining polynomials for five particularly interesting old sextic fields.

Consider first the transitive group $S_{3 \text { gal }}$. Sextic $S_{3 \text { gal }}$ fields are in bijection with cubic $S_{3}$ fields via twinning, i.e. via Galois closure in this case. Hence, the $S_{3 \text { gal }}-d$ entry on Table 5 must be just the $S_{3}-d$ entry. The cases with $G^{t}=S_{4}, A_{4}, S_{5}$, and $A_{5}$ are similarly trivial.

Consider next the transitive group $C_{6}$. These fields are in bijection with ordered pairs of appropriate fields $\left(L_{3}, L_{2}\right)$ by twinning, i.e. by tensor product in this case. So the $C_{6}-d$ entry on Table 5 is the product of the $A_{3}-1$ entry and the $S_{2}-d$ entry, i.e. just $1 \cdot 1=1$. The cases with $G^{t}=A_{3} S_{3}$ and $A_{4} S_{2}$ are similarly trivial.

Now consider the transitive group $G=C_{3}^{2} . V$ with twin group $G^{t}=S_{3} S_{3}$. By twinning $C_{3}^{2} . V-d$ sextics are in bijection with ordered pairs $\left(L_{a}, L_{b}\right)$ of $S_{3}$ cubics with discriminant classes satisfying say $d_{a}<d_{b}$ and $d_{a} d_{b}=d$. The simple "multiplication" table below lets one easily deduce the desired numbers. For example, there are five $C_{3}^{2} . V$ sextics of discriminant class 2 , corresponding to the sum of the
boldface table entries.

|  | $d_{b}$ | -6 | -3 | -2 | -1 | 6 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| $d_{a}$ | $\#$ | 1 | 4 | 1 | 1 | 1 |
| -6 | 1 |  | $\mathbf{4}$ | 1 | 1 | 1 |
| -3 | 4 |  |  | 4 | 4 | 4 |
| -2 | 1 |  |  |  | $\mathbf{1}$ | 1 |
| -1 | 1 |  |  |  |  | 1 |
| -6 | 1 |  |  |  |  |  |

Sextic fields with group $G=S_{2}{l^{+}}^{+} S_{3}$ are in bijection with quartic fields with group $S_{4}$; there are thus 22 of them, as indicated by Table 5 . Similarly, consider sextic fields with group $G=S_{2}$ 乙 $S_{3}$ and discriminant class $d$. Since $G^{t}=S_{4} S_{2}$, these fields are in bijection with quartic fields with group $S_{4}$ and discriminant class different from $d$. Thus, for example, there are $22-3=19$ sextic fields with group $S_{2} \backslash S_{3}$ and discriminant class $d=6$. This finishes our completeness proof.

To save space, we do not tabulate all 282 old sextics here. Tables are currently available from $[\mathbf{J}]$. We wish however to emphasize that these fields $K$ are of some interest as well, not everything being immediately deducible from knowledge of the twin algebra $K^{t}$. For example, the integers arising as class numbers of $S_{2}$ l $S_{3}$ sextics are $1,2,3,4,6,7,8,12$, and 24 . Since large class numbers are often of particular interest we list the five fields giving the four largest class numbers.

| $h$ | Cl | $d$ | Irreducible Sextic | $\leftrightarrow$ | Reducible Sextic |
| ---: | :--- | :---: | ---: | :--- | :--- |
| 7 | $C_{7}$ | -2 | $x^{6}+15 x^{4}+48 x^{2}+32$ | $\leftrightarrow$ | $\left(x^{4}-24 x^{2}+32 x+24\right)\left(x^{2}+3\right)$ |
| 8 | $C_{4} C_{2}$ | -3 | $x^{6}+18 x^{4}+72 x^{2}+48$ | $\leftrightarrow$ | $\left(x^{4}-24 x^{2}+32 x+24\right)\left(x^{2}+2\right)$ |
| 8 | $C_{4} C_{2}$ | -6 | $x^{6}+9 x^{4}+18 x^{2}+6$ | $\leftrightarrow$ | $\left(x^{4}-24 x^{2}+32 x+24\right)\left(x^{2}+1\right)$ |
| 12 | $C_{6} C_{2}$ | -6 | $x^{6}-6 x^{4}+96$ | $\leftrightarrow$ | $\left(x^{4}-6 x^{2}+8 x+6\right)\left(x^{2}-3\right)$ |
| 24 | $C_{12} C_{2}$ | -3 | $x^{6}+6 x^{4}-18 x^{2}+12$ | $\leftrightarrow$ | $\left(x^{4}+8 x-6\right)\left(x^{2}-6\right)$ |

All these fields are totally imaginary. The quartic polynomial $x^{4}-24 x^{2}+32 x+24$ is our preferred defining polynomial for the unique totally real $S_{4}$ quartic. In general the unique cubic subfield of an $S_{2} 2 S_{3}$ sextic is the resolvent cubic of the associated-by-twinning quartic. So, the cubic subfield of the first three fields is totally real; thus these three fields are CM fields.
3.3. Table of new sextics. Table 6 has two lines for each of the twenty-eight $D_{4}$ fields and each of the four $C_{4}$ fields. The $D_{4}$ fields come in seven groups of four, each group being listed in an order $F, F^{t}, F^{T}$, and $F^{t T}$. Here one of the four $D_{4}$ quartics $F$ is followed by its twin, its twist, and its twin-twist. The twin $F^{t}$ is defined to be the unique quartic field which is distinct from $F$ but has the same Galois group as a quotient of $\operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{Q})$. Twisting refers to replacing the permutation representation $\rho: \operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{Q}) \rightarrow D_{4}$ by the different permutation representation $\rho \chi$ where $\chi: \operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{Q}) \rightarrow Z \subset D_{4}$ is a quadratic character with values in the center $Z$ of $D_{4}$. The subfields of the four fields have the form $\mathbb{Q}(\sqrt{s})$, $\mathbb{Q}\left(\sqrt{s^{t}}\right), \mathbb{Q}(\sqrt{s})$, and $\mathbb{Q}\left(\sqrt{s^{t}}\right)$ for $s, s^{t}$, $s s^{t}$ distinct in $\{-6,-3,-2,-1,2,3,6\}$. These four fields have all been put on the $d=s s^{t}$ subtable. Similarly, all four $C_{4}$ quartics have been put on the $d=1$ subtable.

The twin pair $\left(F, F^{t}\right)$ is followed by twin pairs of $C_{3}^{2} . D_{4}$ sextics $\left(K_{a}, K_{a}^{t}\right)$, $\left(K_{b}, K_{b}^{t}\right), \ldots$. Here $F$ is the resolvent quartic for $K_{a}, K_{b}, \ldots$ while $F^{t}$ is the

Table 6. New sextic fields

resolvent quartic for $K_{a}^{t}, K_{b}^{t}, \ldots$. Correspondingly, the twin pair $\left(F^{T}, F^{t T}\right)$ is followed by twin pairs of $C_{3}^{2} . D_{4}$ sextics associated to it. Similarly, each $C_{4}$ quartic is followed by the twin pairs of $C_{3}^{2} . C_{4}$ sextics for which it is the resolvent. Next come the $S_{6}$ or $A_{6}$ sextics in twin pairs. Note that much of the information about $K^{t}$ can be deduced from the corresponding information about $K$. We have printed the $K^{t}$ information in accordance with our general policy that redundancy is acceptable if it improves clarity; here the tables make it clear how sextic twinning works on a practical level, both locally and globally.

The entries in the $S C_{p}$ slots are slightly different from those in Table 1. For a pair of twin fields, we print the slope content as before for the first field. For its twin we print the Galois mean slopes to two decimal places for $p=2$ and $p=3$. Recall from $\S 1.2$ that these are rational numbers $\alpha$ and $\beta$ satisfying $\operatorname{grd}(K)=2^{\alpha} 3^{\beta}$.

Similarly, the labeling convention here is slightly different from the convention in Table 1. We label $p$-adic fields of degree $\leq 5$ just as before, to distinguish among fields with the same invariants ( $f^{e}, c_{w}, d, s$ ). Old sextic $p$-adic fields are typically not determined by their invariants ( $f^{e}, c_{w}, d, s$ ). The worst case is sextic 3 -adic fields with $\left(f^{e}, c_{w}, d, s\right)=\left(1^{6}, 11_{k},-3,-3\right)$, where there are 15 different fields. These old fields are distinguished by the invariants - including labels - of their twin algebras; accordingly we do not label old sextic fields. There are no new sextic 2-adic fields; there are 12 new sextic 3 -adic fields, which we label when necessary as before.

There are many patterns to be found on Table 6 . Here we just make one comment about the solvable sextics and one about the non-solvable sextics.

New solvable sextics. This comment is point-by-point analogous to the comment made in $\S 1.3$. For the thirty-two $G=C_{4}$ or $D_{4}$ quartic fields $F$, the 2decomposition group $\operatorname{Gal}\left(F_{2}\right)$ is always $G$ itself. Up to conjugation the only subgroups of $C_{3}^{2} . G$ surjecting onto $G$ are $C_{3}^{2} \cdot G$ itself and $G \subset C_{3}^{2} . G$. Since there is no surjection from $\operatorname{Gal}\left(\overline{\mathbb{Q}}_{2} / \mathbb{Q}_{2}\right)$ onto $C_{3}^{2} . G$, the 2-decomposition group $\operatorname{Gal}\left(K_{2}\right)$ for all the new solvable sextics $K$ is just $G$. In fact $K_{2} \cong F_{2} \times L_{2}$ where $L_{2}$ is the unique quadratic subfield of $F_{2}$. This accounts for the repetitiveness of the 2-local block of columns.

New non-solvable sextics. The tables show that the 62 new non-solvable sextics, besides being unramified outside $\{\infty, 2,3\}$, are all ramified at $\infty$, and all wildly
ramified at 2 and 3 . In fact, at 2 the largest possible order of the wild inertia group $P_{2}$ allowed by local conditions is 8 . For 30 of the 31 pairs one has $\left|P_{2}\right|=8$; the lone exception is our first-listed $A_{6}$ pair which has $\left|P_{2}\right|=4$. At 3 , the largest possible order of $P_{3}$ is 9 . Again for 30 of the 31 twin pairs in fact $\left|P_{3}\right|=9$; the lone exception is our first-listed $d=6$ pair with $\left|P_{3}\right|=3$.
3.4. Completeness by class field theory. Let $F$ be one of the twentyeight $D_{4}$ quartics or one of the four $C_{4}$ quartics with discriminant $-{ }^{j} 2^{a} 3^{b}$. Here we use class field theory to determine the number of $C_{3}^{2} . D_{4}$ or $C_{3}^{2} . C_{4}$ sextics with discriminant $-{ }^{j} 2^{a} 3^{b}$ and resolvent quartic $F$. The results prove that our computer search, which was not guaranteed to find all the $C_{3}^{2} . C_{4}$ and $C_{3}^{2} . D_{4}$ sextics, in fact did.

Let $L \subset F$ be the unique quadratic subfield and $\sigma \in \operatorname{Gal}(F / L)$ be the involution fixing exactly $L$. Let $\widetilde{K}$ be a maximal abelian pro-3-extension of $F$ ramified only in $S=\{\infty, 2,3\}$. The field $\widetilde{K}$ is the compositum over $F$ of two disjoint subfields $\widetilde{K}^{+}$and $\widetilde{K}^{-}$. Here $\sigma$ acts trivially on $G_{3}^{+}:=\operatorname{Gal}\left(\widetilde{K}^{+} / F\right)$ and by inversion on $G_{3}^{-}:=\operatorname{Gal}\left(\widetilde{K}^{-} / F\right)$.

Let $\tilde{\sigma} \in \operatorname{Gal}\left(\widetilde{K}^{-} / L\right)$ be any lift of $\sigma \in \operatorname{Gal}(F / L)$. Let $H \subset G_{3}^{-}$be a subgroup of index 3 . For clarity we remark that $\left[\widetilde{K}^{H}: \mathbb{Q}\right]=12$. However more to the point, one has $\left[\widetilde{K}^{H, \tilde{\sigma}}: \mathbb{Q}\right]=6$. The map

$$
\begin{aligned}
\left\{\text { index } 3 \text { subgroups of } G_{3}^{-}\right\} & \rightarrow\{\text { Sextic fields with resolvent quartic } F\} \\
H & \mapsto \widetilde{K}^{H, \tilde{\sigma}}
\end{aligned}
$$

is always surjective. It is moreover 1-to-1 if $\operatorname{Gal}(F)=D_{4}$ and 2-to-1 if $\operatorname{Gal}(F)=C_{4}$.
We are thus reduced to describing the abelian group $G_{3}^{-}$modulo cubes. In fact, in each case we will describe $G_{3}^{-}$itself. Let $U_{3}^{(1)} \subset F_{3}^{\times}$be the group of 3-adic 1-units. Let $E \subset F^{\times}$be the group of global units, $E^{(1)}$ the subgroup of global units which are 1 -units at 3 , and finally $E_{3}^{(1)}$ its 3 -adic completion. The involution $\sigma \in \operatorname{Aut}(F / \mathbb{Q})$ acts, decomposing both $E_{3}^{(1)}$ and $U_{3}^{(1)}$ into a (+)-eigenspace and a $(-)$-eigenspace.

For each of our quartic $C_{4}$ or $D_{4}$ base fields, the class number is prime to 3 as can be seen from the tables in $\S 3.3$. There are two $D_{4}$ fields where the 2 -adic units have non-trivial pro-3 completion, namely those with $f=2$ and $e=2$ at 2 . Here the pro- 3 completion is just $\mathbb{F}_{4}^{\times} \cong \mathbb{Z} / 3$. However the quadratic subfield $L$ has $f=2$ and $e=1$, and so this $\mathbb{Z} / 3$ contributes to $G_{3}^{+}$and not $G_{3}^{-}$.

Class field theory gives an idelic description of $G_{3}^{-}$. Because of the vanishing described in the previous paragraph, this idelic description reduces to the 3 -adic description

$$
G_{3}^{-}=\operatorname{Coker}\left(\phi: E_{3}^{(1)-} \rightarrow U_{3}^{(1)-}\right)
$$

In each case, one knows $E_{3}^{(1)-}$ abstractly from Dirichlet's theorem. Similarly, it is easy to determine $U_{3}^{(1)-}$ abstractly from the $D_{4}$ and $C_{4}$ entries in the tables in $\S 3.3$. Also, it follows from general principles that the groups $E_{3}^{(1)-}, U_{3}^{(1)-}$, and $\operatorname{Coker}(\phi)$ are isomorphic for a dihedral quartic field $F$ and its twin $F^{t}$.

For the thirty-two ground fields $F$ in question, only four pairs of abstract groups $\left(E_{3}^{(1)-}, U_{3}^{(1)-}\right)$ arise, according to which we divide into cases $A-D$ :

|  | $E_{3}^{(1)-}$ | $U_{3}^{(1)-}$ | Minimal Coker | $\mid C_{3}^{2} \cdot D_{4}$ Fields $\mid$ | $\mid C_{3}^{2} . C_{4}$ Fields $\mid$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $A$ | $\mathbb{Z}_{3}^{2}$ | $\mathbb{Z}_{3}^{2}$ | $\{0\}$ | $\mathbf{0}, 1,4$ | $\mathbf{0}, 2$ |
| $B$ | $\mathbb{Z}_{3}$ | $\mathbb{Z}_{3}^{2}$ | $\mathbb{Z}_{3}$ | $\mathbf{1}, 4$ |  |
| $C$ | $\mathbb{Z}_{3}$ | $\mathbb{Z}_{3}^{2}+\mathbb{Z} / 3$ | $\mathbb{Z}_{3}+\mathbb{Z} / 3$ | $\mathbf{4}, 13$ |  |
| $D$ | $\{0\}$ | $\mathbb{Z}_{3}^{2}$ | $\mathbb{Z}_{3}^{2}$ | $\mathbf{4}$ | $\mathbf{2}$ |

The four cases match up with the $C_{4}$ and $D_{4}$ ground fields as they are listed in $\S 3.3$ as shown here:

| -6 | -3 | -2 | -1 | 1 | 2 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{C}$ | $C$ | $B$ | $B$ | $A$ | $\mathbf{A}$ |
| $B$ | $B$ | $B$ | $B$ | $D$ | $D$ |
|  |  |  | $B$ | $D$ |  |
|  |  |  | $B$ | $A$ |  |
|  |  |  | $B$ |  |  |
|  |  |  | $C$ |  |  |

Thus the first twin pair of $D_{4}$ quartics for $d=-6$ lie in Case $C$ and so on. The cases worked out below correspond to the entries in boldface.

The entries in the $\mid C_{3}^{2} . D_{4}$ Fields $\mid$ column give the number of $C_{3}^{2} . D_{4}$ fields corresponding to various possible cokernels. The smallest number is printed in boldface; this is the number of $C_{3}^{2} . D_{4}$ fields if and only if the map $\phi$ is as surjective as possible, yielding the minimal cokernel tabulated. Similar remarks apply to the $\mid C_{3}^{2} . C_{4}$ Fields $\mid$ although there are fewer possibilities.

Note that the number of fields found by the computer search is always the number in boldface. Thus, proving that the table is complete is equivalent to proving the following proposition.

Proposition 3.1. For each of the 32 quartic ground fields $F$ in question, the cokernel of $\phi: E_{3}^{(1)-} \rightarrow U_{3}^{(1)-}$ is minimal.

Of course, in Case $D$ there is nothing to prove. As remarked, for the dihedral cases $A-C$ we have only to prove the statement either for $F$ or $F^{t}$. This leaves 15 cases, which we considered separately.

In each of these cases, we presented $F$ by an even polynomial

$$
F=\mathbb{Q}[x] /\left(x^{4}+a x^{2}+b\right)
$$

The involution $\sigma$ then acts simply by $\sigma(x)=-x$. We then used Pari to find one or two global units in the group $E_{3}^{(1)-}$, either $u_{1}$ in Cases $B$ and $C$ or $u_{1}, u_{2}$ in Case $A$. We then verified that $u_{1}$ or $u_{1}, u_{2}, u_{1} u_{2}, u_{1} / u_{2}$ are not cubes in $U_{3}^{(1)-}$. For this last step it suffices to work modulo a sufficiently large power of 3 . Note, Pari can be pushed to guarantee a basis for global units, and the $u_{i}$ we obtained most likely form a basis of $E_{3}^{(1)-}$. However, in this case it is unnecessary to know the value of $\phi$ applied to a basis of $E_{3}^{(1)-}$. We need only know that there exist global units which are not cubes, as described above. We now outline two typical calculations.

Typical Case $C$ computation. Consider the first pair of $D_{4}$ twins in the table for discriminant class -6 . We worked with $F=\mathbb{Q}[x] /\left(x^{4}-2 x^{2}+3\right)$. Here $\mathcal{O}_{F}=\mathbb{Z}[x]$. Both $F$ and its quadratic subfield are totally imaginary so $E_{3}^{+}$and $E_{3}^{-}$have ranks 0 and 1 respectively, the latter group containing $v=x^{3}+x^{2}-x-2$. One has the factorization $x^{4}-2 x^{2}+3=\left(x^{2}+3\right)\left(x^{2}+4\right) \in \mathcal{O}_{F} / 9$. This corresponds to the factorization into quadratic rings $\mathcal{O}_{F_{3}}=\mathbb{Z}_{3}[\sqrt{-3}] \times \mathbb{Z}_{3}[\sqrt{-4}]$ given on the tables. The factor $\mathbb{Z}_{3}[\sqrt{-3}]$ has third roots of unity and thus contributes $\mathbb{Z}_{3} \times \mathbb{Z} / 3$ to $U_{3}^{(1)-}$. On the other hand the factor $\mathbb{Z}_{3}[\sqrt{-4}]$ contributes $\mathbb{Z}_{3}$ to $U_{3}^{(1)-}$. Thus indeed we are in Case $C$.

The residue fields for $\mathbb{Z}_{3}[\sqrt{-3}]$ and $\mathbb{Z}_{3}[\sqrt{-4}]$ are $\mathbb{F}_{3}$ and $\mathbb{F}_{9}$ respectively. Thus, to insure we have a 1-unit, we let $u=v^{8}$ and so

$$
\begin{aligned}
u & =-4904 x^{3}-9024 x^{2}-2792 x+4225 \\
& \equiv x^{3}+3 x^{2}+7 x+4 \quad(\bmod 9)
\end{aligned}
$$

Let $\bar{x}$ be the image of $x$ in the unramified factor $\mathbb{Z}_{3}[\sqrt{-4}]$; so $\bar{x}$ is a unit and satisfies the congruence $\bar{x}^{2}+4 \equiv 0(\bmod 9)$. The image of $u$ in $\mathbb{Z}_{3}[\sqrt{-4}]$ is the 1-unit $3 \bar{x}+1$. Since 3 is a uniformizer, the cube of any 1-unit in $\mathbb{Z}_{3}[\sqrt{-4}]$ is congruent to 1 modulo 9. Hence $3 \bar{x}+1$ is not a cube in $\mathbb{Z}_{3}[\sqrt{-4}]$, and we conclude that $u \in E_{3}^{(1)-}$ is not a cube in $U_{3}^{(1)-}$.

Typical Case $A$ computation. Consider the first $D_{4}$ field from the tables with discriminant class 2. Then $f(x)=x^{4}-6 x^{2}+3$, an Eisenstein polynomial for $p=3$. Thus, $\mathcal{O}_{F_{3}}=\mathbb{Z}_{3}[x]$ and $x$ is a local uniformizer. Since $F$ is totally real, $E_{3}^{+}$has rank 1 and $E_{3}^{-}$has rank 2. The group $E_{3}$ contains $v_{1}=x^{3}+x^{2}-5 x-4$, $v_{2}=x^{3}+2 x^{2}-x-1$, and $v_{3}=x^{3}-2 x^{2}-x+1$. It is easy to check that $\sigma\left(v_{1}\right) v_{1}=1$. We then anti-symmetrize $v_{2}$ to produce $v_{2} / \sigma\left(v_{2}\right)=-2 x^{3}-4 x^{2}+2 x+1$. Taking squares to produce 1-units (since the residual degree is clearly 1 ), we have $u_{1}=v_{1}^{2}=-6 x^{3}-4 x^{2}+34 x+25$ and $u_{2}=\left(v_{2} / \sigma\left(v_{2}\right)\right)^{2}=76 x^{3}+176 x^{2}-44 x-95$.

In this case we work modulo $x^{6}$. A brief computation shows that elements of $\mathcal{O}_{F_{3}} /\left(x^{6}\right)$ can be written uniquely in the form $a x^{3}+b x^{2}+c x+d$ where $a$ and $b$ are taken modulo 3 , and $c$ and $d$ are taken modulo 9 . It is easy to compute the cube of this expression; cubes are of the form $c^{3} x^{3}+3 c d^{2} x+d^{3}$. Reducing the units above modulo $x^{6}$, we find

$$
\begin{aligned}
u_{1} & \equiv 2 x^{2}+7 x+7 \\
u_{2} & \equiv x^{3}+2 x^{2}+x+4 \\
u_{1} u_{2} & \equiv 2 x^{3}+2 x^{2}+2 x+4 \\
u_{1} / u_{2} & \equiv 2 x^{3}+1 .
\end{aligned}
$$

Thus each expression is not a cube $\bmod x^{6}$, hence not a cube in $U_{3}^{(1)-}$.
ADDED IN PROOF: We have now incorporated into our programs the improvements described in $\S 2.5$. We have obtained analogous complete lists for sextics ramified within other small sets of primes. The case of $\{\infty, 2,3\}$ septics also has been completed. Tables, similar in format to Table 1 and Table 6 , are available at $[\mathbf{J}]$.
